DIFFUSION WEIGHTED IMAGE (DWI) AND MAGNETIC RESONANCE SPECTROSCOPY (MRS) OF MASS LIKE LESIONS IN THE BRAIN AS CORRELATED TO HISTOPATHOLOGY.

Pichest METARUGCHEEP,[1] Suchart PHUDHICHAROENRAT,[2] Nitat KIATHIRANNON,[1] Somsak CHANYAWATTIWONGES[1]

ABSTRACT

Bachground and purpose:

DWI and MRS have been used for the differentiation and grading of the brain tumors for more than 10 yrs. We attempted to study the diagnostic efficacy of these two techniques in MR imaging as correlated to the histopathology.

METHODS

Seventy patients with mass like lesions diagnosed by conventional MRI and pathologically or clinically proved (11 low grade astrocytomas and 10 high grade astrocytomas, 7 metastases,3 lymphomas, 2 germinomas,1 medulloblastoma, and 1 neuroblastoma, as well as 17 meningiomas, 5 schwannomas and 13 non tumors) and 20 normal controls were prospectively evaluated with conventional MRI, MRS (Press TR1500 and TE135) and DWI(b=0,500and 1000 s/mm2)

RESULTS

MRS shows diagnostic efficacy in differentiate tumor from non-tumor($p<0.5$), benign from malignant ($p<0.5$) and intraaxial from extraaxial tumor. Cho/CR more than 1.3 is the key value for differentiate of tumor from non-tumor and increase frequency in lactate or lipid may be used for differentiate of malignant from benign tumor. The Cho mono peak is the characteristic of extraaxial tumor.The present of the alanin is the feature of meningioma. ADC values were not effective for grading tumor or to differentiate malignant from benign and tumor from non-tumor. Only restricted diffusion (low ADC value) were noticed in 2 brain abscesses but the number of case is too small.

INTRODUCTION

Conventional MRI is the most useful technique in the diagnosis and evaluation of mass like lesion in the brain. For some instances, it is ineffective. MRS have been used for detection of brain abnormality with nearly 100% sensitivity and differentiate of tumor types by characterization of metabolic changes.[2-24] DWI and ADC (apparent diffusion coefficients) have been used to distinguish normal white matter from necrosis, cyst formation, edema and solid enhancing tumor.[24-33] DWI were also very effective in grading

ADC = Apparent Diffusion Coefficient, **DWI** = Diffusion Weighted Image, **MRS** = Magnetic Resonance Spectoscopy, **CHO** = Choline, **CR** = Creatine, **b** = diffusion Strength, **s** = second

tumor and in the demarcation of tumor by directional dependence of molecular diffusion.[25,28,29,34-38] In this study we attempted to evaluate the effectiveness of MRS and DWI for the differential diagnosis of mass like lesion in the brain. The main purposes were as follows: 1) to differentiate tumor from non-tumor. 2) to differentiate malignant from benign. 3) to do the grading of the tumor and 4) to distinguish pathologic subtypes by correlation of the MRS and ADC parameters with histopathologic findings.

METHODS

Study population:

70 patients comprising 40 men and 30 women ranging from 15 to 75 years of age (means age 45 yrs) with mass like lesion of the brain on conventional MRI were prospectively evaluated with DWI and MRS. 57 cases were pathological proved to be tumor and 13 were non-tumor. 20 normal control study were also done.

MRI evaluation:

All patients were examined by 1.5-Tesla MR imager (Magnetom vision plus, Seimens, Erlangen, Germany) with a standard head coil and protocol axial T1W(TR/TE=650/14 ms), T2WFSE(2000/80 ms) and Flair (TR/TE/TI=9000/2500/110 ms), 5 mms slice thickness, 210 mms FOV and 160x256 matrix size. DWI were done at tumor and peritumoral area and MRS at only tumor area (solid part) as well as other normal looking part.

MRS evaluation:

MRS were obtained by single voxel, PRESS sequence (TR/TE=1500/135 ms) with one-pulse water suppression and avoiding contamination from scalp fat, 256 acquisitions and automatic shimming. Spectroscopic data is from cubic volumes of 1.5x1.5x1.5 cms and acquisition time about 6.30 minutes.

MR diffusion imaging:

DWI were obtained by using axial echo-planar SE sequence (TR/TE=5700/139 ms), 5 mms slice thickness, 96x128 matrix size, FOV 240 mms in 22 seconds. The DWI were acquired by using b values of 0, 500, 1000 s/mm^2 applied in the X,Y, Z directions. Post processing of the ADC maps was performed by using software on a workstation and standard mean ADC values calculated automatically and expressed in 103 mm^2/s.

Histopathologic classification:

Total resection or multiple biopsy specimens were obtained from each patient. The tumor type and grading was according to WHO classification of nervous system tumors. For statistic analysis, lesions were classified as tumor or non-tumor, benign or malignant and high or low grade tumor.

Statistic analysis:

The mean and standard deviation (SD) of all MRS and ADC values were calculated with SPSS. Data were analyzed with independent sample T-test to compare mean of tumor versus non-tumor, benign versus malignant and high versus low grade tumor. The mean different was significant at the level of $p<.05$.

RESULTS

Seventy patients were screwed to the inclusion criteria comprising of 40 men and 30 women,age ranging from 15 to 75 yrs (mean age 45

ADC = Apparent Diffusion Coefficient, **DWI** = Diffusion Weighted Image, **MRS** = Magnetic Resonance Spectoscopy, **FOV** = Field of view, **b values** = Diffusion Strength, **PRESS** = Point Resolved Spectroscopy, **NAA** = N- Acitylaspartate **shimming** = Processes to make the magnetic field not variable, **SPSS** = Computer program for calculating different parameters in statistics such as, means, standard deviations, etc.

years). Fifty seven patients (81%) were tumors and thirteen patients(19%) non-tumors. Base on the histopathologic classification, 24/57(42%) were malignant (10 high grade astrocytomas, 7 metastases, 3 lymphomas, 1 medulloblastoma, 1 neuroblastoma and 2 germinomas) and 33/57 (58%) were benign (11 low grade astrocytomas, 17 menigiomas, 5 schwannomas). The 13 non-tumors were cerebral infarct 6, cysticercosis 3, abscess 2 and multiple sclerosis 2. The MRS showed that it is beneficial for differentiating tumor from non-tumor, malignant from benign, and extraaxial from intraaxial tumor. The most significant parameters were the Cho/Cr value with cut point at 1.3 and the presence of lactate or lipid, Cho/Cr more than 1.3 favored tumor and less than 1.3 favored non-tumor. Malignant tumor showed more frequent lactate and lipid. The character of choline mono peak was found only in extraaxial tumor which helped to differentiate from intraaxial tumor.The Alanin was present only in meningioma. The ADC values were not useful in the differentiating tumor from non-tumor, malignant from benign, or in the grading of the tumor. However, restricted diffusion with low ADC value was noted in both of the brain abscesses and MS.(Table 1)

MR spectroscopic findings:

MRS shows benefit to differentiate the tumor from non-tumor, malignant from benign tumor ($p<.05$). (Table 3&4). The most significant parameter to differentiate tumor from non-tumor is the Cho/Cr value with cut point at 1.3. Malignant tumor shows more Cho/Cr value but less NAA/Cr ratio. In grading of the tumor in the same type such as glioma, the MRS parameter shows no efficacy to differentiate(Table 5). The more frequency of lactate or lipid in malignant tumor (Table 7) is the parameter to differentiate malignant from benign tumor. The present of Alanin in only meningioma can used to be the character of this tumor (Table 6) as well as the Cho mono peak which was seen in other extraaxial tumnor such as Schwannoma as well.

Table 1: Summary of histopathologic diagnosis

Tumor group	Histodiagnosis	No of patients (n=70)
Malignant or high grade(n=24)	Astrocytoma grade 3,4 or GBM	10

DWI and calculated ADC values

The ADC values in both tumor and peri tumor area were not useful in the differentiation tumor from non tumor, malignant from benign or in grading of the tumor(Table 2,3,4). Between subtypes of the tumor they also shows no efficacy, as shown in table 5. Only 2 restricted diffusion were noted in the brain abscesses, but the number of cases are too small.

DISCUSSION

DWI and MRS have been used in the evaluation of brain tumor for more than 10 years. Lower ADC values were accepted as a marker of high tumor grades.[24-39] NAA as marker of neuronal integrity, increase in Cho involved in increased cell membrane and myelin turn over as well as Cr represent cellular energetic and osmotic balance were reported. [2,3,6,8,12,17,18,22,40] Presence of the lactate and lipid were compatible with aggressiveness of the tumor, reflecting increase anaerobic metabolism and cellular necrosis, respectively. [2,3,6,7,9,12,17,18,22,40] The diagnostic accuracy of MRS in differentiate patients from control subjects was 0.96, and neoplasm from non-neoplasm was 0.96 and 0.83 in non blinded and blinded study, respectively.[41]

In our study ,the MRS could differentiate tumor from non-tumor and malignant from benign tumor but not effective in grading tumor. This is along with study by Nail et al.[1] The Decrease in NAA/Cr and incresse Cho/CR is the parameter for differentiate tumor from non-tumor. More malignant tumor shows more increase in Cho/Cr consistent with previous reports.[2,4,10,18,20,23] The increase Cho/Cr was mainly due to increase membrane turn over and liberation of unbound Cho-containing compound caused by destruction of neurons during malignant process, rather than decrease of the Cr level, which is rather constant in many conditions.[2,3,7,12] We also noticed more frequency of lactate or lipid in malignant tumor than benign tumor. This is also consistent with many reports.[7,10,12,23] Presence of lactate the indicator of non functional normal oxidative respiratory and increase anaerobic glycolysis[18] and it represented a loss of normal brain parenchyma and necrosis on MR image.[3] An increase in lipid level has been reported as the indicator of necrosis and usually prominent in non astrocytic tumors and metastasis.[7-9,13,22,23] We detected alanin in 12 of 17 meningioma close to the findings of Nail et al.[1] This could be the specific findings of meningioma. The alanin /Cr ratio in meningeal cells were three to four time higher in that found in astrocytes, neuron and oligodendrocytes.[12]

Krabbe et al[25] found that ADC of contrast enhancing areas and edema surrounding cerebral metastasis were significant higher than those of high grade astrocytoma and Kono et al[32] demonstrated a good correlation between ADC and cellularity in glioma, but in our study shows no different of the ADC in the tumor or peri tumor between malignant and benign as well as high and low grade tumor. Only restricted diffusion with marked low ADC was noticed in two brain abscesses compatible with the study by Noguchi et al.[30] Cho mono peak were found in nearly all extra axial tumor (Meningioma and Schwannoma) and this feature could be used to differentiate extraaxial from intraaxial tumor.

CONCLUSION

MRS showed diagnostic efficacy in differentiating tumor from non-tumor ($p<0.5$), benign from malignant tumors ($p<0.5$) and intraaxial from extraaxial tumors. Cho/CR more than 1.3 was the key value for the differentiation of tumor from non-tumor. The increased frequency in lactate or lipid might be used for differentiation of malignant from benign tumors. The Choline mono peak was the characteristic of extraaxial tumor. The presence of the alanin was the feature of meningioma. ADC values were not effective for grading tumor or differentiating malignant from benign tumor, and tumor from non-tumor, but restricted

diffusion (low ADC value) was noticed in brain abscess.
